

Today's Content

1. Class & Object Basics
2. Linked list Intro
3. Create Linked list 1.. N
4. Search Linked list
5. Size of Linked list

Class: It is a blueprint

Object: Instance / Creation of class

: A single class can have multiple objects.

Class → Attributes / Variables: Property of class

Class → Functions / Methods: Behavior of class

class Car {

 inf: Attributes

 string colour;

 string brand;

 int price;

 Functions:

 accelerate()

 AC()

 music()

};

Car : Suhana

colour: red

brand: BMW

price: 1cr

Functions:

accelerate()

AC()

music()

Car : Shaquib

colour: Black

brand: Ferrari

price: 5cr

Functions:

accelerate()

AC()

music()

Note:

1. Each Object will have its own copy of attributes
2. Function created in class are shared across attributes

Note:

1. Class can have only attributes
2. Class can have only functions
3. Class can have only Attributes / Functions

class creation in C++

class student{

public: # By default all members in class are private;

int m₁, m₂;

int total();

{ return m₁ + m₂; }

Default Constructor added.

If there is no constructor by user side

J: student(); #

j missed at end In C++

main() {

Obj: 1

student s₁;

s₁.m₁ = 10;

s₁.m₂ = 20

int n = s₁.total();

printf("%d"); #30

stack

heap

main:

s₁ [m₁: 10
m₂: 20]

#adr

m₁: 40
m₂: 60

s₂: #adr

Obj: 2

student *s₂ = new student();

Only pointer will create
reference created object

s₂ → m₁ = 40

s₂ → m₂ = 60

Arrow operator to access member of class by pointer

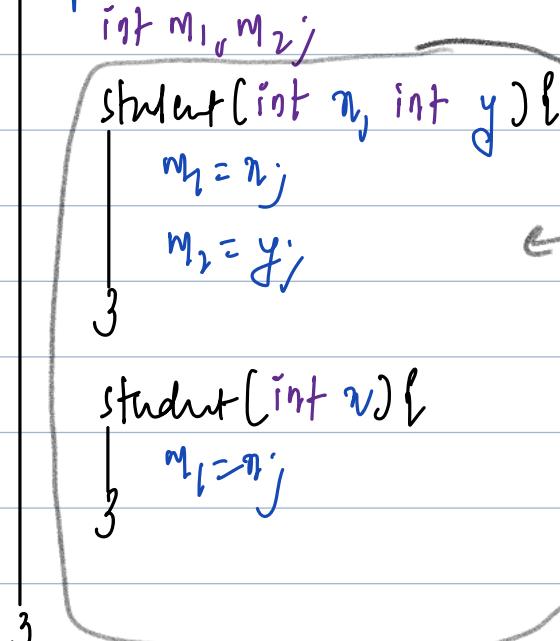

printf(s₂ → total()); #100

Constructor In Class:

1. Just like function, no return type & name same as class name
2. We can only call constructor which exist.

```
class student {
public:
```

Note: If we add constructor, default constructor will not be added.

stack heap

main:

$s_1 = \#ord1$

$\#ord1$

$m_1: 40$

$m_2: 60$

$s_2 = \#ord2 \rightarrow \#ord2$

$m_1: 30$

$m_2: 60$

$s_3 = \#ord3 \rightarrow \#ord3$

$m_1: 40$

$m_2:$

main() {

student *s1 = new student();

$s_1 \rightarrow m_1 = 40;$

$s_1 \rightarrow m_2 = 60;$

student *s2 = new student(30, 60);

student *s3 = new student(40);

student *s4 = new student(); # Errr.

No suitable for Datastructure like Linked List / Tree) - - -

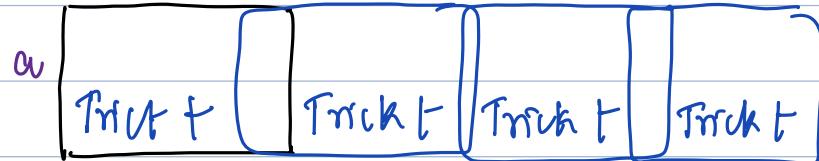

class trick {

public:

trick t;

3 main() {

 trick a;

#Object reference as member.

class Node {

public:

int data;

Node *next;

Node(int n) {

data = n;

} next = nullptr; #In Java = NULL;

3)

main() {

Node *h = new Node(10);

print(h); #addr;

Node *t = h;

t->next = new Node(20);

Address is stored in next of t

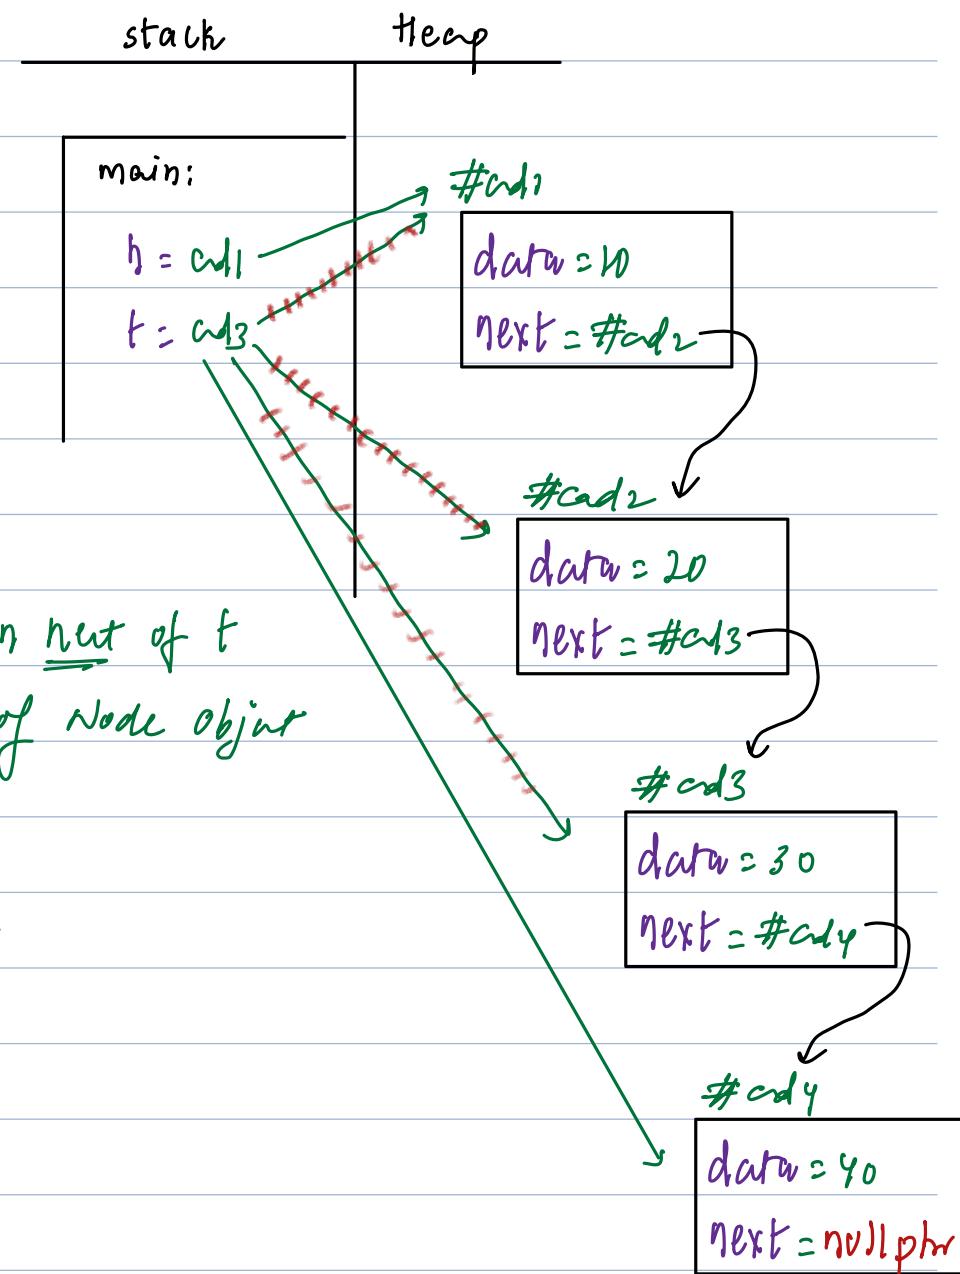

Node * can store address of Node object
t = t->next;

t->next = new Node(30);

t = t->next;

t->next = new Node(40);

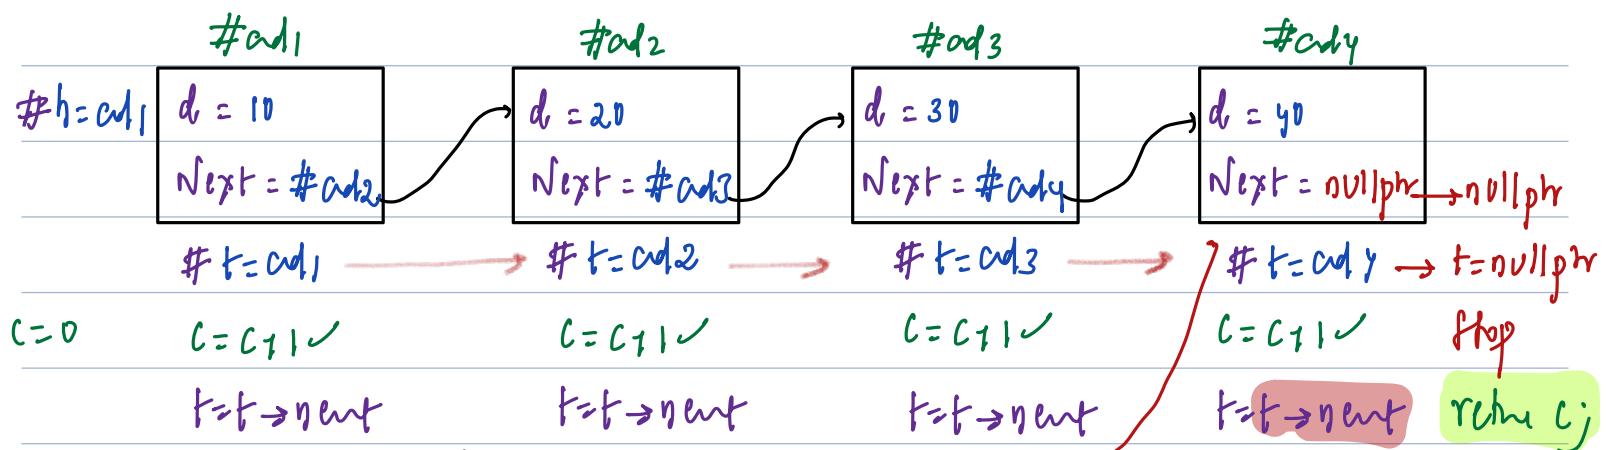

3 t = t->next;

#Obs1: Advantage of nullptr as it will indicate reach of end

#Obs2: If we have head node address we can traverse entire linked list

Q Given a head Node of a linked list, return size of it.

int size(Node *h) {

Node *t = h;

int c=0;

while ($t \neq \text{nullptr}$) {

 c=c+1;

 t=t->next;

}

return c;

}

Code 2 # Will not cover last node

Node *t = h;

int c=0;

while ($t \rightarrow \text{next} \neq \text{nullptr}$) { $\# \text{nullptr} \rightarrow \text{next} \neq \text{nullptr}$ }

 c=c+1;

 t=t->next;

}

return c;

$\# t = \text{nullptr}$

$\# \text{fails RTE.}$

Code 3

En: $h = \text{nullptr}$; \downarrow

Node * $t = h$; $\# t = \text{nullptr}$

int c = 1; $\# c = 1$

while ($t \rightarrow \text{next} \neq \text{nullptr}$) { $\# \text{nullptr} \rightarrow \text{next} \neq \text{nullptr}$
 $\# \text{fails RTE.}$

$c = c + 1$;

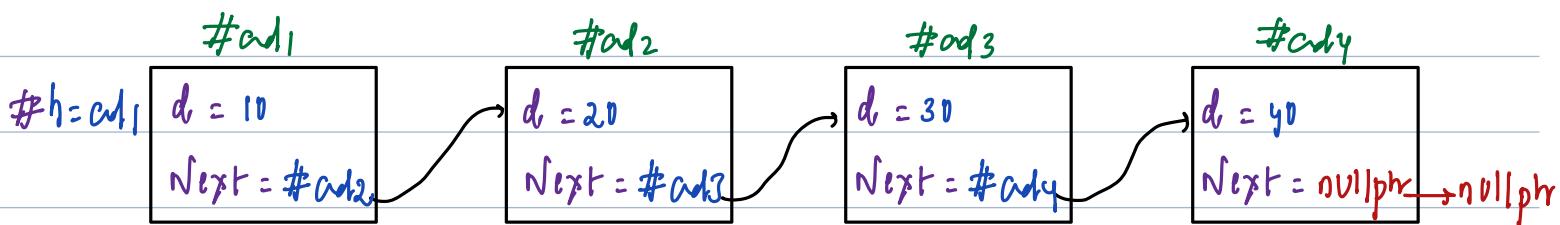

$t = t \rightarrow \text{next}$

3

return c;

Make sure $t \neq \text{nullptr}$

Before we access $t \rightarrow \text{data}$ or $t \rightarrow \text{next}$;

$t = \text{ad1};$

$\text{print}(t)$ $\# \text{ad1}$

$\text{print}(t \rightarrow \text{next})$ $\# \text{ad2}$ $\#$ it won't effect t ;

$\text{print}(t \rightarrow \text{next} \rightarrow \text{next})$; $\# \text{ad3}$

$\text{print}(t \rightarrow \text{next} \rightarrow \text{next} \rightarrow \text{data})$; $\# 30$

if ($t \neq \text{nullptr}$ & $t \rightarrow \text{next} \neq \text{nullptr}$)

Before we access $t \rightarrow \text{next} \rightarrow \text{data}$ or $t \rightarrow \text{next} \rightarrow \text{next}$;
